---

### Assess if Haemoglobin studies required? Obtain Hb studies* if Black African or MCV <=80 fL and MCH <=27 pg and not tested before, unless documented to have been normal previously.

---

### Assess if actively bleeding, exclude dilutional anaemia. Undertake additional B12, Folate testing. Establish if haemolysis is present.

---

* Hb studies can be requested as ‘add-on’ to FBP

---

**Hb >110g/L and ferritin >30ug/L**

- Routine ANC and monitoring
- Iron rich diet

**Hb >110g/L and ferritin, ≤ 30ug/L**

- Commence at least 65mg elemental oral iron daily.
- Iron rich diet

**Hb >70g/L and ≤ 110g/dL and ferritin ≤ 30ug/L**

- Requires medical review to assess cause of anaemia i.e. dilutional anaemia following blood loss, thalassaemia, anaemia chronic disease, or iron deficiency with coexisting inflammatory disease or infection (↑CRP).

**Hb >70g/L and ≤ 110g/dL and ferritin > 30ug/L**

- Requires medical review to assess cause of anaemia i.e. dilutional anaemia following blood loss, thalassaemia, anaemia chronic disease, or iron deficiency with coexisting inflammatory disease or infection (↑CRP).

**Hb <70g/L Irrespective ferritin level**

- Refer to Haematologist for urgent review if pregnant.
- Urgent medical review if postpartum
**BACKGROUND INFORMATION**

Anaemia in pregnancy is defined as an Hb <110 g/L in the first and last trimester, and a Hb <105 g/L in the second trimester. Women with anaemia in pregnancy may experience fatigue, reduced energy levels, reduced mental performances, and in cases of severe anaemia it is associated with preterm birth, low birth weights, and a small for gestational age fetus. In the postpartum period anaemia has been found to be linked to depression, emotional instability, stress and lower cognitive performance tests.

The most common causes of anaemia in pregnancy include iron deficiency, folate deficiency vitamin B12 deficiency, haemolytic diseases, bone marrow suppression, chronic blood loss and underlying malignancies. 30-50% of women become anaemic during pregnancy, with iron deficiency being the most common form of anaemia in more than 90% of the cases.

The gastrointestinal tract increases iron absorption when the body's iron stores are low, and it reduces the absorption when there are sufficient stores. Requirement for absorbed iron ranges from 0.8mg/day in the first trimester to 7.5 mg/day in the second trimester, averaging approximately 4.4 mg/day in pregnancy. Iron requirements increase rapidly in the second and third trimester due to fetal growth, however iron absorption in the gut is not sufficient to meet this increased demand. Thus iron balance depends on maternal iron stores during this period.

A trial of oral iron should be considered as a diagnostic test for all pregnant women with suspected iron deficiency anaemia (IDA). The haemoglobin should increase within 2 weeks, otherwise further tests are required. Oral iron supplementation is the primary treatment option. A high iron diet should be recommended, including red meats (if possible), fortified cereals and drinks. Intravenous iron should only be

*Denotes patients considered high risk of iron depletion or in whom tolerance levels for anaemia should be raised and includes: Twin pregnancy, refusal blood components, teenage pregnancy, presence of co-morbidities, history of anaemia, bleeding disorders, planned home birth, poor compliance to ANC, malabsorption, thrombocytopenia

---

**Assessing response to treatment**

Repeat FBP 2 – 8/52 following commencement of iron therapy (Dependent upon gestation)

- Hb ↑ continue therapy
- Hb ↔ review diet, Fe (type/dose), exclude folate, B12 deficiency (treat as required). Assess if Hb studies required/completed. Refer to CNC Haematology for IV Fe if no improvement in 2nd/3rd trimester only
- Hb ↓ clinical review patient, exclude active bleeding, folate, B12 deficiency (treat as required). Assess if Hb studies required/completed. Refer to CNC Haematology for IV Fe in 2nd/3rd trimester only

---

Title: Anaemia in Pregnancy and the Postnatal Period
Clinical Guidelines: Obstetric and Midwifery

All guidelines should be read in conjunction with the Disclaimer at the beginning of this section

King Edward Memorial Hospital for Women
Perth, Western Australia

2013
used in severe cases of iron deficiency, if the woman is unresponsive to oral iron
treatment, or when rapid repletion of iron is required.\textsuperscript{2,6,7}

\textbf{KEY POINTS}

1. All women should be offered screening for anaemia:
   - in first trimester (or at booking)
   - with the next screening bloods (usually performed between 24-28 weeks)
   - and at 36 weeks gestation

2. A FBP should be ordered within 2 - 8 weeks following initiation of treatment
   (dependent upon gestation) to assess response and compliance with oral iron
   treatments.

3. IDA in most circumstances is diagnosed by a full blood examination and serum
   ferritin levels. Do not use serum iron, or serum ferritin alone to diagnose IDA.\textsuperscript{9}
   NB: Ferritin levels are elevated in active infection or inflammation and in these
   cases concurrent measurement of C-reactive protein (CRP) will support
   interpretation of ferritin levels.\textsuperscript{6}

4. Seek the advice of a Haematologist in diagnosing and treating IDA in women with
   known haemoglobinopathies. Serum ferritin should be checked prior to starting
   iron with known haemoglobinopathy.\textsuperscript{6}

5. Oral iron if taken at the appropriate dose, and for a sufficient time, is an effective
   first-line treatment for most women in pregnancy.\textsuperscript{2,6,7,8,9}

6. If a women fails to respond to iron therapy further investigation is indicated to
   assess for malabsorption problems, non-compliance with medications, co-existing
   disease\textsuperscript{10}, or an incorrect diagnosis.\textsuperscript{10}

7. Parenteral (intramuscular or intravenous) iron enhances haematological response
   compared to oral iron, but there is insufficient data on adverse effects e.g. severe
   allergic reactions or venous thrombosis.\textsuperscript{4}

8. Intravenous iron polymaltose therapy is an effective alternative to oral treatment
   during the second or third trimester only for treatment of IDA. Intravenous iron
   should only be used in women failing to respond to oral iron treatment with known
   IDA or in those whom a rapid repletion of iron stores is required.

9. The type, dosage, and frequency of iron supplements for treatment of IDA should
   be documented in MR 220 ‘Pregnancy Health Record’.

10. At each antenatal visit all women taking iron supplements should be monitored for
    medication compliance and side-effects.

11. Women with a normal Hb and ferritin levels < 30\mu g/L should be commenced on
    oral iron supplements in pregnancy to prevent development of anaemia. A dosage
    of at least 65mg elemental iron should be taken once daily.\textsuperscript{6}.
**INTERPRETING SERUM BLOOD RESULTS FOR ANAEMIA IN PREGNANCY**

Please note that some Pathology Laboratories report results using non-pregnant adult reference ranges, when interpreting results. Use the reference ranges in the table below as a guide.

<table>
<thead>
<tr>
<th>BLOOD RESULT</th>
<th>INTERPRETATION</th>
<th>ADDITIONAL INFORMATION</th>
</tr>
</thead>
</table>
| Hb: < 110 g/L (1st & 3rd trimester) | Anaemia in pregnancy | The CDC definition of anaemia is:  
- Hb <110 g/L in the first and last trimester  
- Hb <105 g/L in the second trimester. |
| Hb<105g/L (2nd trimester) | Anaemia in pregnancy |  |
| Hb: ≤ 110g/L (postpartum) | Anaemia in the post-partum period |  |
| Ferritin levels\(^2\):  
  - < 30µg/L  
  - < 15µg/L | Indicates a low iron status – i.e. small or no iron reserves \(^3\)  
Indicates depletion of iron stores \(^3\) | Elevated ferritin levels also occur with inflammation, infection, liver disease, malignancy \(^7\), and lead poisoning. \(^2\) |
| Mean corpuscular volume (MCV). | Low MCV indicates small cells (microcytosis) and associated with IDA. \(^9\) High MCV is associated with folate and B12 deficiency. | Haemoglobinopathy risk should be assessed and excluded. \(^5,9\)  
MCV can be normal in early IDA, or with coexisting vitamin B\(_{12}\) or folate deficiency. |
| Transferrin, or total iron binding capacity. | High levels are associated with IDA. Levels are normal with thalassaemia minor. \(^9\) | Levels can be normal in early IDA. |
| Transferrin saturation | Low levels are associated with IDA. Normal or elevated levels are associated with thalassaemia minor. \(^9\) |  |
| Serum iron | Low levels are associated with IDA. Levels are normal in thalassaemia minor. \(^9\) |  |
| Serum B\(_{12}\) | Levels below 200pmol/L indicate B\(_{12}\) deficiency. \(^11\) |  |
| Serum folate | Levels < 7 nmol/L indicate folate deficiency. \(^12\) | Severe folate deficiency in pregnancy can result in megaloblastic anaemia. \(^10\)  
Multiple pregnancy increases the demand for folate. Alcohol and some drugs may interfere with absorption e.g. anticonvulsants and |
IRON DEFICIENCY ANAEMIA IN PREGNANCY

DEFINITION USED FOR DIAGNOSIS AT KEMH
For management purposes at KEMH iron deficiency anaemia in pregnancy is diagnosed when the:
- Hb <110 g/L in the first and last trimester
- Hb <105 g/L in the second trimester.

Mild iron deficiency anaemia results in a Hb between 90-105 g/L in 2nd trimester, 90-109g/dL in 1st and 3rd trimester.
More severe iron deficiency may result in a more significant anaemia with a Hb < 90g/dL.

**Note**

Lower dosage iron supplements can be effective for treatment of IDA, and are associated with less gastrointestinal side-effects. However it is recommended in...
confirmed iron deficiency states, that treatment with oral ferrous iron (100 – 200mg daily) is required to correct the deficiency.²,⁶ Clinical staff should be familiar with the iron content of freely available supplements women take in pregnancy, as many contain insufficient elemental iron to be therapeutic.⁷.

**Prescribing Iron Supplements and Follow-up**

All women with IDA should be advised:
- the type, frequency, and duration of the treatment or medication
- side-effects of the medication which can exacerbate the symptoms of pregnancy including heartburn, nausea, vomiting and constipation
- management of side-effects
- how and when to take the medications
- of medications or food that may inhibit iron absorption
- dietary information to increase oral iron intake

Provide written instructions to the woman about iron supplementation - KEMH brochure – Iron Supplements.

At each antenatal visit:
- assess and document the woman for compliance with taking the medication
- assess and document side-effects from the medication. Provide advice for management of any side-effects
- assess compliance to dietary recommendations

**Dietary Information**

Sources of dietary iron include meat, poultry and fish which are two to three times more absorbable than plant-based iron foods and iron-fortified foods.⁵ Meat, poultry and fish increase absorption of iron,⁸ and ascorbic acid provides an enhancing effect on absorption.⁵,¹³,¹⁷ Orange juice is often recommended in pregnancy, although some iron supplement contain Vitamin C.⁵ Vegetarians should be encouraged to eat foods high in iron, such as, tofu, beans, lentils, spinach, whole wheat breads, peas, dried apricots, prunes and raisins.¹⁷ Foods or medications that interact or inhibit iron absorption Medications inhibiting absorption or contraindicated include:

- anticonvulsants¹³
- sulphonamides¹³
- medications that raise gastric pH e.g. antacids (avoid where possible) ¹⁸
- Dietary inhibitors may include:
  - calcium in dairy products e.g. cheese⁸,¹⁰,¹⁷
  - tea and coffee⁸,¹⁷,¹⁹
  - chocolate
  - spinach and beetroot⁸
  - soy products¹⁰
• phytates (salts found in plants capable of forming insoluble complexes with iron) e.g. bran, cereal.\textsuperscript{18}

Non-haem iron requires an acidic pH to be reduced to ferrous for gut absorption. A gap of 2 hours from dietary or medication inhibitors of iron absorption appears to be sufficient to avoid the problem.

\textit{Side-effects of oral medications and management}

When oral liquid iron is used it should be diluted with water and a straw used to prevent discolouration of the teeth. However, liquid iron supplements should be checked for the content of elemental iron.

Side-effects of oral iron supplements include nausea, epigastric pain, constipation\textsuperscript{13},\textsuperscript{19} and black discolouration of the faeces.\textsuperscript{19}

Management for side effects include:

• nausea and epigastric discomfort – take iron tablets on an empty stomach 1 hour prior to or 2 hours after a meal, commence tablets on a low dosage and then gradually increase the amount or iron, or take small doses more frequently.

• constipation – see Clinical Guideline Minor symptoms or disorders in pregnancy.

\textbf{ANAEMIA AND HAEMOGLOBINOPATHIES}

See Clinical Guideline Haemoglobinopathies Screening and Referral

\textbf{ANAEMIA AND VITAMIN B\textsubscript{12} DEFICIENCY}

Vitamin B\textsubscript{12} deficiency is uncommon in pregnancy as it is often associated with infertility.\textsuperscript{5} As it is required for synthesis of new DNA the demand in pregnancy increases by up to ten times.\textsuperscript{11} It is generally only found in foods of animal origin,\textsuperscript{12} therefore deficiency is more likely to occur in women who are vegetarians’ or vegans. These women are recommended to take supplementation during pregnancy.\textsuperscript{20} If deficiency is not treated in pregnancy it can lead to neurological sequelae in exclusively breastfed infants.\textsuperscript{21}

management

1. Women who follow a vegetarian diet should have their vitamin B\textsubscript{12} levels checked in early pregnancy.

2. Women who are vegetarians are recommended to have vitamin B\textsubscript{12} supplements during pregnancy and lactation.\textsuperscript{21} Malabsorption problems can also lead to deficiency in vitamin B\textsubscript{12}.\textsuperscript{12}

3. Treatment for vitamin B\textsubscript{12} deficiency is intramuscular Cobalamin 1000mcg daily for 1 week followed by Cobalamin 1000mcg of monthly injections. In strict vegans, it is recommended 3 monthly injections of Cobalamin 1000 mcg be administered.\textsuperscript{11}

4. Neonatal review should be arranged prior to discharge if a mother is diagnosed with Vitamin B\textsubscript{12} deficiency in pregnancy.
ANAEMIA AND FOLATE DEFICIENCY

Folate is required for DNA synthesis so demand increases by up to ten times in pregnancy. Deficiency can develop rapidly as stores are minimal. Deficiency in folate can cause megaloblastic anaemia which is found in 5% of pregnancies. Anaemia is more likely to be found later in pregnancy due to the rapidly growing fetus, and primarily occurs as a result of reduced dietary intake or poor absorption. The recommended dietary allowance in pregnancy is 600µg/day, and most commonly prescribed prenatal vitamins contain 800µg which is more than the recommended dose. Meat is not a good source for folate, however folate can be found in green leafy vegetables, legumes and orange juice.

MANAGEMENT

Women at risk of folate deficiency (e.g. multiple pregnancy, haemolytic anaemia) should take 5 mg of folic acid throughout the pregnancy.

OTHER CAUSES OF ANAEMIA

Microangiopathic anaemia can be seen in pregnancy conditions such as preeclampsia, eclampsia, HELLP syndrome, and with thrombotic thrombocytopenia purpura. Autoimmune haemolytic anaemia occurs up to four times more frequently in pregnancy. Other causes of anaemia in pregnancy include malaria, hookworm infections and HIV.
